Christian Schröder‡      Françoise Tisseur†

December 22, 2011

## Abstract

This is the Users' Guide for NLEVP: a collection of nonlinear eigenvalue problems provided in the form of a MATLAB toolbox. A separate paper describes the collection and its organization.

## 1 Introduction

This document describes how to install and use the NLEVP MATLAB toolbox, which provides a collection of nonlinear eigenvalue problems.

For details of the design and organization of the collection, and the problems it contains, see [1].

This document describes 3.0 of the toolbox. The collection will grow and contributions are welcome (see Section 6).

## 2 Installation and Usage

The collection is available from

<http://www.mims.manchester.ac.uk/research/numerical-analysis/nlevp.html>

It is provided as both a zip file and a tar file. To install the toolbox create the directory `nlevp` in a suitable location and make it the current directory. Download `nlevp.zip` or `nlevp.tar` into this directory. Then use appropriate “unzip” software (making sure to preserve the directory structure) or type `tar xvf nlevp.tar`. This creates the subdirectory `private`. Put the `nlevp` directory on the MATLAB path, which can be done using the `addpath` command (ideally in `startup.m`). If you are using GNU Octave then you must also put the `nlevp/private` directory on the path.

To try the toolbox, run the demonstration script by typing `nlevp_example` at the MATLAB command prompt. Then execute the following commands:

```
help nlevp
nlevp query problems
```

```

nlevp query properties

nlevp help railtrack
nlevp query railtrack
coeffs = nlevp('railtrack')
spy(coeffs{2})

coeffs = nlevp('bicycle')
polyeig(coeffs{:})

```

The collection has been tested in MATLAB versions 7.1 (R14) up to R2011b. It does not work with versions 6.5 (R13) and earlier of MATLAB, since it uses functionality introduced in MATLAB 7.0 (R14).

## 3 Release History

### 3.1 First Release, 1.0

The first release of the toolbox was version 1.0, dated 4-Apr-2008, and contained 26 problems.

### 3.2 Second Release, 2.0

The second release, version 2.0, was dated 15-Nov-2010, contained 46 problems, and had the following changes:

- Problem `string` has been renamed `spring`. `spring` has been generalized to include more parameters but is backward compatible with `string`. Invoking `nlevp('string')` still works: it invokes `nlevp('spring')` and produces a warning message.
- The matrices generated by problems `acoustic_wave_1d` and `acoustic_wave_2d` have been modified in order to more closely match the formulation in the paper from which this problem is taken. The eigenvalues now lie in the upper half-plane instead of the left half-plane.
- New problems are: `fiber`, `foundation`, `genhyper2`, `Hadeler`, `intersection`, `metal_strip`, `pdde_stability`, `plasma_drift`, `omnicam1`, `omnicam2`, `qep1`, `qep2`, `qep3`, `qep4`, `railtrack2`, `relative_pose_5pt`, `relative_pose_6pt`, `shaft`, `speaker_box`, `surveillance`.
- New functionality: `nlevp('eval',...)` and `[coeffs,fun] = nlevp('name',...)`.
- Automatic testing of problem properties via `nlevp_test`.
- Cosmetic changes have been made to some of the functions.
- Citations to the sources of the problems have been updated, where necessary.

### 3.3 Third Release, 3.0

The third release, version 3.0, is dated 22-Dec-2011, contains 52 problems, and has the following changes:

- New problems `gen_tantipal2`, `gen_tpal2`, `mirror`, `planar_waveguide`, `qep5`, `time_delay`.
- For scalable problems the first dimension parameter now specifies the size,  $n$ , of the coefficient matrices (or an approximation to it). Previously,  $n$  was a function of this parameter in some cases. It is now possible to generate all scalable problems of a given size (or approximately that size). A warning message, with identifier `NLEVP:truescale`, is printed when the affected problems are called.
- Scalable problems now return coefficient matrices in the MATLAB `sparse` format when the coefficient matrices are sparse.

- A new problem property `random` has been introduced to specify problems that use random numbers in their construction. Such problems include an optional input argument that is used to seed the random number generator, which is useful for generating a repeatable sequence of problem instances. If that optional input argument is not provided then the same (fixed) problem is generated each time, while an argument `'noseed'` ensures that the random number generator is not seeded. A random number seed argument has been added to `gen_hyper` and may result in different matrices being generated than with previous versions of NLEVP. All problems with the `random` property can use either the old or new (`rng`) MATLAB syntax for seeding the random number generator, as chosen through an input argument.
- `dirac` has been vectorized. The coefficients may differ at the level of rounding error from those produced by the previous, unvectorized code.
- The first two input arguments of `spring_dashpot` have been interchanged, so that the first is the dimension.
- A bug in the computation of the derivatives of the `gun` problem has been corrected.
- This release is compatible with GNU Octave [2], as far as possible. It has been tested with Octave 3.2.4 under Windows and Octave 3.4.3 under Linux. Since Octave does not have a function `polyeig` the function `nlevp_example` will not run.

## 4 The MATLAB Function `nlevp`

The toolbox has just one main user-callable function, `nlevp`, which is as follows.

```
function varargout = nlevp(name,varargin)
%NLEVP    Collection of nonlinear eigenvalue problems.
% [COEFFS,FUN,OUT3,OUT4,...] = NLEVP(NAME,ARG1,ARG2,...)
% generates the matrices and functions defining the problem specified by
% NAME (a case insensitive string).
% ARG1, ARG2,... are problem-specific input arguments.
% All problems are of the form
%   T(lambda)*x = 0
% where
%   T(lambda)= f0(lambda)*A0 + f1(lambda)*A1 + ... + fk(lambda)*Ak.
% The matrices A0, A1, ..., Ak are returned in a cell array:
% COEFFS = {A0,...,Ak}.
% FUN is a function handle that can be used to evaluate the functions
% f1(lambda),...,fk(lambda). For a scalar lambda,
% F = FUN(lambda) returns a row vector containing
%   F = [f1(lambda), f2(lambda), ..., fk(lambda)].
% If lambda is a column vector, FUN(lambda) returns a row per element in
% lambda.
% [F,FP] = FUN(lambda) also returns the derivatives
%   FP = [f1'(lambda), f2'(lambda), ..., fk'(lambda)].
% [F,FP,FPP,FPPP,...] = FUN(lambda) also returns higher derivatives.
% OUT3, OUT4, ... are additional problem-specific output arguments.
% See the list below for the available problems.
%
% PROBLEMS = NLEVP('query','problems') or NLEVP QUERY PROBLEMS
% returns a cell array containing the names of all problems
% in the collection.
% NLEVP('help','name') or NLEVP HELP NAME
% gives additional information on problem NAME, including number and
% meaning of input/output arguments.
% NLEVP('query','name') or NLEVP QUERY NAME
```

```

% returns a cell array containing the properties of the problem NAME.
% PROPERTIES = NLEVP('query','properties') or NLEVP QUERY PROPERTIES
% returns the properties used to classify problems in the collection.
% NLEVP('query',property1,property2,...) or NLEVP QUERY PROPERTY1 ...
% lists the names of all problems having all the specified properties.
%
% [T,TP,TPP,...] = NLEVP('eval',NAME,LAMBDA,ARG1,ARG2,...)
% evaluates the matrix function T and its derivatives TP, TPP,...
% for problem NAME at the scalar LAMBDA.
%
% NLEVP('version') or NLEVP VERSION
% prints version, release date, and number of problems
% of the installed NLEVP collection.
% V = NLEVP('version')
% returns a structure V containing version information.
% V consists of the fields v.number, v.date, and v.problemcount.
%
% Available problems:
%
% acoustic_wave_1d Acoustic wave problem in 1 dimension.
% acoustic_wave_2d Acoustic wave problem in 2 dimensions.
% bicycle 2-by-2 QEP from the Whipple bicycle model.
% bilby 5-by-5 QEP from Bilby population model.
% butterfly Quartic matrix polynomial with T-even structure.
% cd_player QEP from model of CD player.
% closed_loop 2-by-2 QEP associated with closed-loop control system.
% concrete Sparse QEP from model of a concrete structure.
% damped_beam QEP from simply supported beam damped in the middle.
% dirac QEP from Dirac operator.
% fiber NEP from fiber optic design.
% foundation Sparse QEP from model of machine foundations.
% gen_hyper2 Hyperbolic QEP constructed from prescribed eigenpairs.
% gen_tpal2 T-palindromic QEP with prescribed eigenvalues on the
% unit circle.
% gen_tantipal2 T-anti-palindromic QEP with eigenvalues on the unit
% circle.
% gun NEP from model of a radio-frequency gun cavity.
% hadeler NEP due to Hadeler.
% hospital QEP from model of Los Angeles Hospital building.
% intersection 10-by-10 QEP from intersection of three surfaces.
% loaded_string REP from finite element model of a loaded vibrating
% string.
% metal_strip QEP related to stability of electronic model of metal
% strip.
% mirror Quartic PEP from calibration of cadioptic vision system.
% mobile_manipulator QEP from model of 2-dimensional 3-link mobile manipulator.
% omnicam1 9-by-9 QEP from model of omnidirectional camera.
% omnicam2 15-by-15 QEP from model of omnidirectional camera.
% orr_sommerfeld Quartic PEP arising from Orr-Sommerfeld equation.
% pdde_stability QEP from stability analysis of discretized PDDE.
% planar_waveguide Quartic PEP from planar waveguide.
% plasma_drift Cubic PEP arising in Tokamak reactor design.
% power_plant 8-by-8 QEP from simplified nuclear power plant problem.
% QEP1 3-by-3 QEP with known eigensystem.
% QEP2 3-by-3 QEP with known, nontrivial Jordan structure.
% QEP3 3-by-3 parametrized QEP with known eigensystem.
% QEP4 3-by-4 QEP with known, nontrivial Jordan structure.

```

```

% QEP5          3-by-3 nonregular QEP with known Smith form.
% railtrack     QEP from study of vibration of rail tracks.
% railtrack2    Palindromic QEP from model of rail tracks.
% relative_pose_5pt Cubic PEP from relative pose problem in computer vision.
% relative_pose_6pt QEP from relative pose problem in computer vision.
% schrodinger   QEP from Schrodinger operator.
% shaft         QEP from model of a shaft on bearing supports with a
%               damper.
% sign1         QEP from rank-1 perturbation of sign operator.
% sign2         QEP from rank-1 perturbation of 2*sin(x) + sign(x)
%               operator.
% sleeper       QEP modelling a railtrack resting on sleepers.
% speaker_box   QEP from finite element model of speaker box.
% spring        QEP from finite element model of damped mass-spring
%               system.
% spring_dashpot QEP from model of spring/dashpot configuration.
% time_delay    3-by-3 NEP from time-delay system.
% surveillance  27-by-20 QEP from surveillance camera calibration.
% wing          3-by-3 QEP from analysis of oscillations of a wing in
%               an airstream.
% wiresaw1      Gyroscopic system from vibration analysis of wiresaw.
% wiresaw2      QEP from vibration analysis of wiresaw with viscous
%               damping.
%
% Examples:
% coeffs = nlevp('railtrack')
%         generates the matrices defining the railtrack problem.
% nlevp('help','railtrack')
%         prints the help text of the railtrack problem.
% nlevp('query','railtrack')
%         prints the properties of the railtrack problem.
%
% For example code to solve all polynomial eigenvalue problems (PEPs)
% in this collection of dimension < 500 with MATLAB's POLYEIG
% see NLEVP_EXAMPLE.M.

## 5 The MATLAB Function nlevp\_example

The toolbox contains a function `nlevp_example.m` that illustrates the use of `nlevp`. Running it provides a quick test that the toolbox is correctly installed. This function can be adapted in order to test the user's own methods on subsets of NLEVP problems.

```

function nlevp_example(fname)
%NLEVP_EXAMPLE Run POLYEIG on PEP problems from NLEVP.
% NLEVP_EXAMPLE solves all the not-too-large PEP problems in NLEVP
% by POLYEIG, sending output to the screen.
% NLEVP_EXAMPLE(fname) directs partial output to the file named fname
% (intended for generating output for NLEVP paper).

if nargin == 0
    fid = 1;
else
    fid = fopen(fname,'w');
end
s_rand = warning('off', 'NLEVP:random'); % For gen_hyper2.

nmax = 500;
probs = nlevp('query','pep');
nprobs = length(probs);
nprobs_total = length(nlevp('query','problems'));
fprintf(fid,'NLEVP contains %2.0f problems in total,\n', nprobs_total);
fprintf(fid,'of which %2.0f are polynomial eigenvalue problems (PEPs).\n', nprobs);
fprintf(fid,'Run POLYEIG on the PEP problems of dimension at most %2.0f:\n\n',nmax);

fprintf(fid,'

```

Problem	Dim	Max and min magnitude of eigenvalues

```

\n');

```

```

fprintf(fid,'          -----  ---  -----\n');
m = ceil(nprobs/4);
j = 1;
for i=1:nprobs
    if fid ~= 1 && i == 9
        fprintf(fid,'          ... \n');
        fid_save = fid;
        fid = 1; % Omit output from this point on when writing to file.
    end
    coeffs = nlevp(probs{i});
    [n, nc] = size(coeffs{1});
    if n >= nmax
        fprintf(fid,'%20s   %3.0f is a PEP but is too large for this test.\n', ...
            probs{i}, n);
    elseif n ~= nc
        fprintf(fid,'%20s   %3.0f is a PEP but is nonsquare.\n', probs{i}, n);
    else

        % POLYEIG will convert sparse input matrices to full.
        e = polyeig(coeffs{:});
        fprintf(fid,'%20s   %3.0f   %9.2e, %9.2e\n', ...
            probs{i}, n, max(abs(e)), min(abs(e)));
        subplot(m,4,j)
        plot(real(e), imag(e),'.')
        title(probs{i}, 'Interpreter', 'none')
        % Tweaks.
        if strcmp(probs{i}, 'sign1'), ylim([-1 1]*1.5), end
        if strcmp(probs{i}, 'damped_beam')
            title(['          ' probs{i}], 'Interpreter', 'none')
        end
        if strcmp(probs{i}, 'relative_pose_6pt')
            title(['          ' probs{i}], 'Interpreter', 'none')
        end
        if strcmp(probs{i}, 'speaker_box') || strcmp(probs{i}, 'intersection')
            title(['          ' probs{i}], 'Interpreter', 'none')
        end
        j = j+1;
    end
end

if nargin > 0, fclose(fid_save); end
warning(s_rand)

```

Part of the output of the function is shown in [1].

## 6 Contributing to the Collection

Contributions of suggested new problems for the collection are welcome. They can be sent to any of the authors. The following rules should be followed when providing new problems.

Write a  $\text{\LaTeX}$  file called `problem_name.tex`, where `problem_name` is the proposed name of your example, describing the problem. Here, `problem_name` should be a string in lower case without any spaces. The `tex` file should consist of a `problem` environment, with first line stating the relevant identifiers for the problem (these properties are listed by `nlevp query properties`, and are explained in the companion document [1]):

```

\begin{problem}{problem_name}{identifier1,identifier2,...}
This is a xxx-problem of dimension nnn.

```

```
It arises in ...
\end{problem}
```

Provide your citations in a `bib` file; one `bib` file suffices even if multiple `tex` files are provided.

Write an M-file generating the coefficients of the example called `problem_name.m`. Document the M-file in the leading comment lines with the most important information from the `tex` file. If the problem is parameter dependent, set default values for any parameters not specified when the function is called. If you need extra data files, their names should begin with `problem_name`, e.g., `problem_name.mat`.

To specify a polynomial problem the first output of the M-file should be a cell array containing the coefficient matrices starting with the constant term. Thus if the first output is called `coeffs` and you want to define a PEP  $P(\lambda) = \sum_{i=0}^k \lambda^i A_i$ , then `coeffs{1}`= $A_0$ , `coeffs{2}`= $A_1$ , ..., `coeffs{k+1}`= $A_k$ .

The second output argument must be a function that computes the nonlinear scalar functions in the definition of the problem and their derivatives; for a polynomial eigenvalue problem this is trivially provided by a line of the form

```
fun = @(lam) nlevp_monomials(lam,k);
```

Here, `nlevp_monomials.m` is a function provided with NLEVP in the `private` directory.

If a supposed solution is provided it should be returned in a structure `sol` with the following format:

`sol.eval`: an  $m \times 1$  vector, where  $m$  eigenvalues are provided,

`sol.evec`: an  $m \times n$  matrix, where column  $j$  is the eigenvector corresponding to `sol.eval(j)`.

If both left and right eigenvectors are known, they should be returned in `sol.evec_left` and `sol.evec_right`.
